20. ABSTRACT (Continue on reverse side if necessary and identify by block number)

This report provides information and analysis on the physical condition of the dam as of the report date. Information and analysis are based on visual inspection of the dam by the performing organization.

Examination of available documents and a visual inspection of the dam did not reveal conditions which constitute an immediate hazard to human life or property. However, the dam has some deficiencies which need to be evaluated and remedied.

10

SECURITY CLASSIFICATION OF THIS PAGE (When Data Entered)

Hydrologic/hydraulic analyses performed in accordance with the Corps of Engineers' Recommended Guidelines for Safety Inspection of Dams indicate that the principal spillway and the emergency spillway would pass 100 percent of the outflow from the Probable Maximum Flood (PMF) without overtopping the dam. Therefore, the combined spillway capacity is adjudged to be adequate.

D

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspections. Detailed investigation and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionary in nature. It would be incorrect to assume that the present condition of the dam will continue to represent the condition of the dam at some point in the future. Only through frequent inspections can unsafe conditions be detected and only through continued care and maintenance can these conditions be prevented or corrected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions thereof. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as necessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

PHASE I INSPECTION REPORT
NATIONAL DAM SAFETY PROGRAM

Name of Dam:	Little Choconut Watershed Site 2B Dam
State Located:	New York
County:	Broome
Watershed:	Susquehanna River Basin
Stream:	Unnamed Tributary of Little Choconut Creek
Date of Inspection:	December 15, 1980

ASSESSMENT

Examination of available documents and a visual inspection of the dam did not reveal conditions which constitute an immediate hazard to human life or property. However, the dam has some deficiencies which need to be evaluated and remedied.

Hydrologic/hydraulic analyses performed in accordance with the Corps of Engineers' Recommended Guidelines for Safety Inspection of Dams indicate that the principal spillway and the emergency spillway would pass 100 percent of the outflow from the Probable Maximum Flood (PMF) without overtopping the dam. Therefore, the combined spillway capacity is adjudged to be adequate.

It is recommended that the following additional investigations be performed by a registered professional engineer engaged by the owner:

1. Determine the stability characteristics and gradation of the riprap material on the channel face of the spur dike, adjacent to the right side of the dam embankment.

2. Determine the physical properties and configuration of the dam embankment Zone 2 material (See page F-5 of Appendix F) and monitor the downstream embankment slope during periods of high storage levels.

These investigations should be initiated within 6 months and completed within 18 months of the final approval date of this report. In the interim, a detailed flood warning and emergency evacuation plan should be developed and implemented.

In addition to any items required as a result of the additional investigations recommended above, the following remedial measures should be implemented to correct the existing deficiencies.

1. Monitor local slumping on the downstream face of the spur dike and determine if remedial measures are required.

2. Mow the grass on the embankment slopes at least annually and clear brush and trees from the slopes and bottom of the emergency spillway channel.

3. Inspect the deteriorated joint filler between the 30 inch principal spillway outlet pipe and the reinforced concrete impact basin to monitor for possible loss of soil.

4. Restore the riprap protection on the left side slope of the emergency spillway channel.

These corrective measures should be completed within 12 months of the final approval date of this report.

SECTION 1 - PROJECT INFORMATION

1.1 GENERAL

a. Authority

The Phase I Inspection reported herein was authorized by the Department of the Army, New York District, Corps of Engineers, to fulfill the requirements of the National Dam Inspection Act, Public Law 92-367. Flaherty Giavara Associates, P.C. has been retained by the New York District to inspect and report on selected dams in the State of New York. Authorization and notice to proceed was issued to Flaherty Giavara Associates, P.C. under a letter of December 24, 1980 from W. M. Smith, Jr., Colonel, Corps of Engineers. Contract No. DACW 51-81-C-0006 has been assigned by the Corps of Engineers for this work.

b. Purpose

Evaluation of the existing conditions of the subject dam to identify deficiencies and hazardous conditions, determine if they constitute hazards to life and property and recommend remedial measures where necessary.

1.2 DESCRIPTION OF PROJECT

a. Description of Dam and Appurtenances

Little Choconut Watershed Site 2B Dam consists of an earthen embankment with a concrete pipe principal spillway under the central portion of the embankment and an emergency spillway channel cut into rock at the right abutment.

It is one of eight floodwater retarding dams in the Little Choconut, Finch Hollow, and Trout Brook watersheds designed to reduce floodwater damages. Plans, profiles and sections prepared for the project by the U.S. Department of Agriculture, Soil Conservation Service (SCS), are shown on drawings in Appendix F.

The dam embankment is approximately 790 feet long angling slightly downstream, 56 feet high and has an upstream slope of 3 horizontal to 1 vertical and a downstream slope of 2.5 to 1. The crest of the dam is 16 feet in width and its elevation varies from 1274.3 to 1275.3 (NGVD). There is a 10 foot wide berm at the toe of the upstream slope just below normal pond level. The embankment cross section is primarily compacted glacial till, with an internal zone of highly fractured shale and siltstone. It has a 12 to 14 foot wide cutoff of compacted glacial till extending 5 to 17 feet below the original ground surface. The cutoff extends into weathered rock under the right abutment slope and into glacial till under the left abutment. The upstream and downstream slopes are provided with grass cover (crown vetch) for erosion protection, except for riprap at the entrance to the emergency spillway and a small area around the principal spillway outlet. The embankment has an internal drain in pervious fill near the downstream toe for over half its length. Two 8 inch diameter perforated bituminous-coated corrugated metal pipes discharge into the impact basin of the principal spillway outlet, one on either side of the outlet pipe.

The principal spillway is a drop inlet structure consisting of a single stage reinforced concrete riser, a 30 inch diameter prestressed concrete cylinder pipe (PCCP) and a reinforced concrete impact basin.

The emergency spillway is a 380 foot long by 55 foot wide channel cut into rock at the right abutment. The left side of the spillway is formed by a spur dike extending approximately 240 feet downstream from the right end of the dam embankment. It has a 12 foot wide crest that varies in elevation from 1267.0 to 1274.4 (NGVD). The right side slope cuts into the rock slope at 1 to 1 up to a bench, then at 2 to 1 up to existing grade; whereas the side slope along the dike forming the left side of the spillway is at 3 to 1. The downhill slope of the dike is 2.5 to 1, and its cross section is primarily glacial till with a zone of broken rock along the channel side. The emergency spillway channel slopes gently downward both upstream and downstream from a 50 foot wide level section (the spillway crest) that is close to the left end of the dam crest. The valley side slope drops steeply down at each end of the channel.

b. Location

The Little Choconut Watershed Site 2B Dam is located off Airport Road approximately one mile northwest of its intersection with New Ireland Road in the Town of Maine, New York. The dam is located at latitude north 42°-10.6'

and longitude west 75°-58.1' on the U.S. Geological Survey 7.5 minute series topographic map "Castle Creek, New York". The Location Map on page i indicates where the dam is situated.

c. Size Classification

The maximum height of the dam is 56 feet and the maximum storage capacity is 305 acre-feet. Therefore, the Little Choconut Watershed Site 2B Dam is classified as an "Intermediate" dam as defined by the Recommended Guidelines for Safety Inspection of Dams.

d. Hazard Classification

There are approximately 2 dwellings within the dam failure flood hazard area. A high voltage transmission line as well as Airport Road and Stella Ireland Road are located downstream of the dam. Therefore, the dam is in the High Hazard category as defined by the Recommended Guidelines for Safety Inspection of Dams.

e. Ownership

The dam is owned by the County of Broome and maintained by the Broome County Soil & Water Conservation District. Their addresses and telephone numbers are as follows:

Owner

Contact: Carl S. Young, Broome County Executive
Broome County Building
Government Plaza
P.O. Box 1766
Binghamton, New York 13902

Telephone: (607) 772-2109

Maintenance

Contact: William Maxian, District Manager
Broome County Soil & Water Conservation District
Farm, Home and 4-H Center
840 Front Street
Binghamton, New York 13905

Telephone: (607) 773-2691

f. Purpose

The primary purpose of this dam is flood control in the Little Choconut Creek watershed to reduce floodwater damages.

g. Design and Construction History

This dam was designed by the SCS between June 1965 and January 1967. It was constructed in 1968 by the Talson Construction Company of Herkimer, New York. No major post construction modifications have been made to the dam.

h. Normal Operating Procedures

The intake riser is always open; therefore, the water level is maintained at the elevation of the crest of the intake weir for normal flows. There are no regular operating procedures.

- Control: None

SECTION 2 - ENGINEERING DATA

2.1 GEOTECHNICAL DATA

a. Geology

The Little Choconut Watershed Site 2B Dam is located in the Appalachian Plateau physiographic province of New York State. The topography of the area ranges from 810 feet in the Susquehanna River to more than 1500 feet in the vicinity of this site. The total relief is less today than it was pre-glacially, owing to aggradation of till on the uplands and valley sides and deposition of outwash and alluvial materials in river channels. This site is a good example of outwash and alluvial materials filling a pre-glacial valley.

Glacial ice had little effect on the topography in this area. The ice sheet was relatively thin, extending only some 40 miles south of the Binghamton area.

The underlying bedrock is Upper Devonian in age and is almost exclusively shales and siltstones of the Catskill Delta.

The geologic history of this site appears to be one of glacial scour of the north-facing valley wall (right abutment) and filling of the pre-glacial valley with lacustrine and alluvial deposits. Apparently, there has been some erosion of the bedrock in the lower elevation of the right abutment. Drill holes (DH) and test pits (TP) reveal the development of a shelf in the bedrock surface at about present stream bed elevation. This situation is further verified by the enhanced steepness of the abutment for a vertical distance of 30 feet or so above this shelf. This condition has been noted on other sites in this area and verified by drilling.

b. Subsurface Investigations

1. Centerline of Dam

The left abutment of this site is a fairly uniform glacial till. This uniformity extends down to the area of the principal spillway, and to a depth of at least 30 feet at DH 51 (See Appendix F - Profiles).

In the floodplain, the till is replaced by a moderately dirty gravel to an average depth of 3 feet. This gravel is underalin by a 3 to 5 foot layer of stiff clay. Under the clay, a moderately thick zone of coarse sand extends to below backhoe depth.

DH 52 went through this sand and back into till, with bedrock being encountered at a depth of approximately 33 feet. Seepage was heavy in backhoe pits excavated in this material during design.

On the right side of the floodplain, the backhoe trench revealed the bedrock surface rising steeply from its location at DH 52 to within about 4 feet of the surface. It forms a definite bench at this level and then follows parallel with the ground surface to a point beyond the emergency spillway excavation. The average depth to bedrock over this entire abutment is about 3 feet.

The bedrock encountered in this investigation is predominantly a siltstone with zones of softer shale. Several thin beds of very fine-grained sandstone are mapped in the type section of this Rhinestreet Formation and were also logged in some of the drill holes on this site. Whereas, the overall picture of bedrock in this section of the state indicates a very gentle dip to the southwest, in this immediate vicinity the strata dip 60° to the southwest at a rate of about 90 feet to the mile.

A well developed set of north-south oriented joints exists in the bedrock in this area. This pattern is intersected by a less well developed east-west trending set.

2. Principal Spillway

The two 20 foot drill holes located in the area of the riser and outlet structure were logged as 11 to 13 feet of very dense till, underlain by 1 to 2 feet of very silty gravel or clay. Below this, dense till was again encountered to a depth of 20 feet. The backhoe pit at the intersection of the center of dam and the principal spillway was also logged as 8 feet of dense till with one large 3 to 4 foot boulder in the pit.

3. Emergency Spillway

The entire spillway area is in the bedrock more fully described under "Centerline of Dam". This rock is overlain by an average depth of 3.5 feet of silty gravel; a glacial till.

2.2 DESIGN RECORDS

This dam was designed by the SCS from 1965 through 1967. As part of the design process, a design report, a geology report

and soils testing were completed for the site. This data is included in Appendix D.

2.3 CONSTRUCTION RECORDS

This dam was constructed in 1968 by the Talson Construction Company of Herkimer, New York. The contract drawings, which were prepared by the SCS, have been updated to reflect "As-Built" conditions and are included in Appendix F. In addition, detailed records kept by the SCS during construction are available at their office in Syracuse, New York.

2.4 OPERATION RECORDS

There were no operation records available for this dam.

2.5 EVALUATION OF DATA

The data presented herein was obtained primarily from the offices of SCS in Syracuse, New York and also from the files of the New York State Department of Environmental Conservation (DEC). This information appears to be reliable and adequate for the purposes of a Phase I Inspection Report.

SECTION 3 - VISUAL INSPECTION

3.1 FINDINGS

a. General

Visual inspection of the Little Choconut Watershed Site 2B Dam was conducted on December 15, 1980. The weather was hazy and the temperature was 20± °F. At the time of this inspection, there was approximately two inches of snow on the crest of the dam; however, the slopes had little or no snow cover. Water was flowing in the principal spillway outlet pipe.

b. Dam

The earthfill embankment of the dam is generally in good condition. There was no visible evidence of settlement, lateral movement, seepage, major erosion, or other serious defects.

The following specific items were noted:

1. A minor slough has occurred on the downstream embankment slope of the spur dike forming the left side of the emergency spillway. The condition is local and may be due to freeze-thaw conditions.

2. The grass has been cut short on the relatively level surfaces, but is about 18 inches high on the embankment and cut slopes (See Photos No. 2, 3, 4, 5, 6 and 7). However, the general absence of brush is indicative of past periodic cutting.

3. Scattered young trees and brush have grown through the riprap, rockfill, and rock cut slopes of the emergency spillway (See Photos No. 8 and 9).

4. Rock fragments have been locally shifted to provide a narrow path up the left slope of the emergency spillway.

5. The toe drains were in good condition. The 6 inch diameter BCCMP draining the left side of the dam embankment was discharging approximately 1± gallons per minute (GPM) into the impact basin (See Photo No. 13).

6. Minor seepage is visible from the natural slope at the entrance to the emergency spillway, and from the rock cut face of the right bank of the spillway. The present condition does not threaten the embankment or the spillway cross section.

7. The crest of the embankment was approximately 6 inches low, 70 feet from the right end. There was no other evidence of settlement or crest movement (See Photo No. 3). This may reflect locally greater settlement of the dam embankment after construction.

c. Principal Spillway

1. Drop Inlet Structure

The reinforced concrete drop inlet structure is in excellent condition (See Photo No. 11). The inlet weir has a trash rack attached to it and was free of debris. A gate stem for a lower level inlet was observed but not operated during the inspection.

2. Principal Spillway Conduit

The visible portions of the 30 inch diameter prestressed concrete cylinder pipe (PCCP) is in good condition. The interior could not be observed due to tailwater conditions and the energy dissipator baffle (See Photo No. 13).

3. Principal Spillway Outlet

The principal spillway conduit discharges at a reinforced concrete impact basin used to dissipate the energy of high velocity discharge. Overall, the structure was in excellent condition (See Photo No. 12); however, some loose riprap has accumulated on the downstream concrete apron and the joint filler between the 30 inch PCCP and the impact basin has deteriorated.

4. Principal Spillway Discharge Channel

The man-made channel below the principal spillway impact basin has a riprap lining near the embankment, and a vegetated lining further downstream (Photo No. 14). The riprap is stable and in good condition. There are several areas of minor erosion on the left bank of the channel, and one area where the channel slope has slumped.

d. Emergency Spillway

The emergency spillway is located on the right abutment and has a bottom width of 55 feet. The bottom and the right side of the emergency spillway are cut into bedrock. The left side is a dike with a riprap and rockfill surface, separating the spillway from the main embankment. The riprap had a typical mean dimension of 6

inches, and provided complete coverage of the surface. Some brush and saplings were growing up through or on the riprap, and should be removed before the riprap becomes dislodged. (See Photos No. 8 and 9).

The approach to the spillway is approximately 100 feet long, and the discharge channel runs past the embankment and then drops down the steep side of the valley to the floodplain (See Photo No. 10).

e. Downstream Channel

The natural channel downstream of the dam has a typical width of 10 to 15 feet, and a normal flow depth of 6 inches. Bedrock outcrops occur along its right side. The bed material is gravel and flaggy cobbles. The channel is stable, with no aggradation or degradation.

f. Reservoir - Storage Pool Area

The left side of the floodwater storage area is bordered by gently sloping fields with scattered trees. Upstream and on the right side a heavily wooded slope becomes moderately steep at and above the design high water level (See Photo No. 15). However, there is no significant probability of landslides into the storage pool affecting the safety of the dam. There are no visible signs of instability or sedimentation problems in the reservoir area.

3.2 EVALUATION OF OBSERVATIONS

The visual inspection revealed some minor deficiencies. The following observations were made:

1. A minor slough was noted on the downstream slope of the spur dike.

2. The grass was cut short on the relatively level surfaces, but is 18± inches high on the embankment and cut slopes.

3. Scattered young trees and brush have grown through the riprap, rockfill and rock cut slopes of the emergency spillway.

4. The joint filler between the 30 inch PCCP and the impact basin has deteriorated.

5. Rock fragments have been locally shifted to provide a footpath up the left slope of the emergency spillway.

6. The left toe drain was discharging into the impact at a rate of about 1± GPM.

7. Some loose riprap has accumulated on the apron of the reinforced concrete impact basin.

8. Several areas of minor erosion were noted on the left bank of the principal spillway discharge channel.

9. Minor seepage was visible from the natural slope at the entrance to the emergency spillway and from the rock cut face of the right side slope of the emergency spillway.

10. The crest of the dam was observed to be 6± inches low, 70 feet from the right abutment.

Based on the visual examination conducted on December 15, 1980, the Little Choconut Watershed Site 2B Dam is considered to be in good condition. Minor deficiencies which have been observed should not have a serious effect on the performance or safety of the structure.

SECTION 4 - OPERATION AND MAINTENANCE PROCEDURES

4.1 PROCEDURES

The normal water surface level is maintained by the crest of the drop inlet structure at elevation 1242.5 (NGVD). No operational procedures are in effect at this time.

4.2 MAINTENANCE OF DAM

The dam is maintained by the Broome County Soil & Water Conservation District. Presently, the following yearly maintenance items are performed:

a. Mowing the dam crest and part of the floodplain; however, the mowing of the slopes of the embankment is only done every three years.

b. Maintenance of riprap.

c. Maintenance of the trash rack on the structure.

d. Inspection of concrete and pipes.

e. Inspection of the dam embankment for seepage.

f. Operation of the gate uses to drain the impoundment.

g. Repairs to fences and roads are made as necessary.

4.3 WARNING SYSTEM

No warning system is now in effect; however, the Broome County Soil & Water Conservation District is in the process of preparing an emergency action plan and warning system for the dam to be implemented in the event of dam failure.

4.4 EVALUATION

The operation and maintenance procedures of the dam and appurtenances are satisfactory. However, increased maintenance efforts are required to correct the minor deficiencies which exist.

SECTION 5 - HYDROLOGIC/HYDRAULIC

5.1 DRAINAGE AREA

The dam is located on an unnamed tributary 5500± feet upstream of Little Choconut Creek. The unnamed tributary joins Little Choconut Creek near New Ireland, approximately six miles upstream of the Susquehanna River at Johnson City, New York.

The watershed (shown on the Watershed Map in Appendix C) consists of 1024 acres (1.60 square miles) of rolling to hilly uplands with typical slopes of 10 percent. Land use within the watershed is primarily agricultural, with extensive open fields and orchards. There are no significant waterbodies or wetlands upstream of the dam.

The watercourse upon which the dam is located is a small perennial stream with a typical flow width of 10 feet and a typical flow depth of 6 inches.

5.2 ANALYSIS CRITERIA

The purpose of the hydrologic/hydraulic analysis is to evaluate the spillway capacity and the potential for overtopping.

The analysis of the spillway capacity of the dam and storage of the reservoir was performed using the Corps of Engineers HEC-1 computer model - Dam Safety Version. The procedure included determining the Probable Maximum Flood (PMF) runoff from the watershed and routing the inflow hydrograph through the impoundment to determine the outflow hydrograph. The unit hydrograph was defined by the Snyder Synthetic Unit Hydrograph method, and the modified Puls routing procedure was incorporated.

The initial rainfall loss was assumed to be 1.0 inches, and the uniform rainfall loss was assumed to be 0.1 inches per hour. In accordance with recommended guidelines of the Corps of Engineers, the Probable Maximum Precipitation (PMP) was 23.5 inches (6 hour duration, 10 square mile area).

The analysis was conducted for both the full PMF and for several fractional PMF conditions. The PMF inflow of 4075 CFS was routed through the reservoir and the peak outflow was determined to be 3954 CFS.

5.3 SPILLWAY CAPACITY

The total outlet capacity is the sum of discharges from the principal spillway and the emergency spillway.

The principal spillway consists of a drop inlet structure, conduit and impact basin. Its flow capacity was evaluated by assuming that its capacity was controlled by the inlet (elevation 1242.5 NGVD), which acts as an orifice during periods of high flow.

The emergency spillway is a 55 foot wide, trapezoidal-shaped spillway cut into rock. The SCS design information indicates the emergency spillway was designed to be used only by a flood event with an average return frequency of more than 100 years.

The stage discharge curve for the combined principal and emergency spillways was obtained from the Soil Conservation Service design report for the stages above and including elevation 1263.0 (NGVD):

Stage (Feet)	Discharge Capacity (CFS)	Element of Structure
1242.5	0	Sediment Pool
1263.0	106	Emergency Spillway Crest
1266.8	1080	Design High Water Level
1274.3	6730	Top of Dam

The total spillway capacity at the top of dam is 6730 CFS.

The principal spillway can pass the peak outflow from a flood equal to approximately 16 percent of the PMF before use of the emergency spillway would be required.

The energy grade line of the PMF discharge would be 7.6 feet above the crest of the emergency spillway. The average flow velocity in the emergency spillway discharge channel would be 14.3 feet per second, which is capable of causing erosion of the riprap on the face of the spur dike at the right end of the dam embankment.

5.4 RESERVOIR CAPACITY

The storage capacity of the reservoir was obtained from the Soil Conservation Service design report, as indicated below:

Stage (Feet)	Storage (Acre-Feet)	Storage (Inches in Runoff)
1242.5	14	0.16
1263.0	212	2.48
1266.8	305	3.57
1274.3	533	6.25

5.5 FLOODS OF RECORD

The maximum floods of record for this dam are summarized below:

Date	Event	Maximum Flood Stage Elevation (NGVD)	Feet Below Crest of Emergency Spillway (El. 1263.0)
9/26/75	Hurricane Eloise	1248.4	14.6
2/24/75	--	1246.8	16.2
6/24/72	Hurricane Agnes	1245.5	17.5

It should be noted that floodwaters have never reached the emergency spillway crest.

5.6 OVERTOPPING POTENTIAL

The results of the HEC-1 DB computer analysis indicate that the crest of the dam is not overtopped by the PMF event. The PMF peak discharge rate of 3954 cfs would occur at a peak flood stage of 1270.6 feet, which is 3.7 feet below the crest of the dam.

The results of the analysis are tabulated below:

Flood Condition	Peak Inflow (CFS)	Peak Outflow (CFS)	Maximum Stage Elevation (NGVD)
0.5 PMF	2037	1947	1268.0
1.0 PMF	4075	3954	1270.6

5.7 EVALUATION

Using the Corps of Engineers' screening criteria for the initial review of spillway adequacy, it has been determined that the dam would not be overtopped by either the full Probable Maximum Flood (PMF) or one half the PMF. Approximately 3.7 feet of freeboard would exist between the PMF maximum water level and the crest of the dam. Therefore, the spillway is adjudged to be adequate.

SECTION 6 - STRUCTURAL STABILITY

6.1 EVALUATION OF STRUCTURAL STABILITY

a. Visual Observations

There was no visible evidence of major settlement, lateral movement or other signs of overall structural instability of the dam during the site examination. However, the pool level was approximately 30 feet below the top of the dam at the time, with the result that the forces tending to cause instability were much lower than design levels. Based on the conditions that were observed, there is no reason to question the static structural stability of the dam.

b. Design and Construction Data

Soil Conservation Service record drawings for the Little Choconut Watershed Site 2B Dam, (See Appendix F) show a configuration and cross section for the dam embankment that generally corresponds to the information presented and analyzed in the SCS Geology Report, dated December 1965; in the memorandum presenting test results and stability analyses, dated March 8, 1966; and in the Design Report, dated September 1966. One apparent difference is the inclusion of a zone of highly fractured shale and siltstone within the dam embankment and extending toward the downstream face. This is depicted on Sheet No. 5 (page F-5) of the "As-Built" drawings, contained in Appendix F.

There is no construction data available to confirm the actual physical properties and configuration of the earth and rockfill in the embankment. However, the earth design properties presented in the SCS reports are considered to be reasonable, and as along as the zone of highly fractured rock has relatively low permeability the dam would be expected to have adequate safety margins with respect to stability under static loading conditions. Additionally, toe drains control the phreatic surface and provide a safe outlet for foundation seepage.

A slope stability analysis was performed by the SCS on the embankment of the dam using the Swedish Circle method and adopted design data (See page D-7 of Appendix D). The results of the analysis are tabulated below:

Location	Slope (H:V)	Conditions	Factor of Safety
Downstream Slope	2.5:1	No drain; no berm; radius = 71.0 feet	2.2

The assumptions and method used are considered reasonable; therefore, the resulting factor of safety is adequate.

c. Seismic Stability

The Little Choconut Watershed Site 2B Dam is located in Seismic Zone 1, and in accordance with recommended Phase I guidelines does not require seismic analysis.

SECTION 7 - ASSESSMENT/RECOMMENDATIONS

7.1 DAM ASSESSMENT

a. Condition

On the basis of the visual examination, the Little Choconut Watershed Site 2B Dam is considered to be in good condition. There were no signs of impending structural failure or other conditions which would warrant urgent remedial action, however, deficiencies were noted which when studied in detail may prove to be of a serious nature.

b. Adequacy of Information

The evaluation of this dam is based primarily on visual examination, reference to available SCS plans, approximate hydraulic and hydrologic computations, and application of engineering judgement. The visual examination was somewhat hampered by low pool level and light snow cover; however, the available information and that which was obtained is adequate for the purposes of a Phase I assessment.

c. Need for Additional Investigations

It is recommended that the following additional investigations be performed by a registered professional engineer engaged by the owner:

1. Determine the stability characteristics and gradation of the riprap material on the channel face of the spur dike at the right end of the dam embankment to ensure that the riprap will not erode during high flow velocities.

2. Conduct a detailed review of construction records to the determine the physical properties and configuration of dam embankment Zone 2 material. If there remains a question as to possible seepage to the downstream face, the embankment slope should be regularly monitored during high storage levels to determine whether corrective measures are necessary.

d. Urgency

The additional investigations recommended in Section 7.1c should be initiated within 6 months and appropriate remedial measures completed within 18 months of the final approval date of this report. In the interim, a detailed flood warning and emergency evacuation plan should be developed and implemented. The recommended measures

presented in Section 7.2 should be carried out by the owner within 12 months of the final approval date of this report.

7.2 RECOMMENDED MEASURES

Although the dam is generally in good condition, it is considered important that the following items be accomplished:

1. Monitor local slumping on the downstream face of the spur dike to determine if continued movements are occurring. If they are, remedial action such as excavating slumping material and replacing it with free-draining material, may be required.

2. Mow the grassed slopes of the dam embankment at least annually and clear brush and trees from the slopes and bottom of the emergency spillway channel.

3. Inspect the deteriorated joint filler between the 30 inch principal spillway outlet pipe and the reinforced concrete impact basin to monitor for possible loss of soil.

4. Restore the left side slope of the emergency spillway channel where rock fragments (riprap) have been shifted to provide a path.

VISUAL INSPECTION CHECKLIST

VISUAL INSPECTION CHECKLIST

1) Basic Data

a. General

Name of Dam Little Choconut Watershed Site 2B Dam

Fed. I.D. # NY 721 **DEC Dam No.** 96A-3630

River Basin Susquehanna

Location: Town Maine **County** Broome

Stream Name Unnamed

Tributary of Little Choconut Creek

Latitude (N) 42°-10.6' **Longitude (W)** 75°-58.1'

Type of Dam Earthen Embankment

Hazard Category High

Date(s) of Inspection December 15, 1980

Weather Conditions Hazy 20±°F.

Reservoir Level at Time of Inspection Elevation 1242.5

b. Inspection Personnel

R.C. Smith, T.L. Ward & J.G. MacBroom of Flaherty Giavara Associates, P.C., P.L. LeCount & J.J. Rixner of Haley & Aldrich Inc., S. Dhawan & L. Comrie of Salmon Associates

c. Persons Contacted (Including Address & Phone No.)

Gary L. Page	Donald W. Lake, Jr.
Binghamton Watershed Office Soil Conservation Service	Soil Conservation Service
P.O. Box 1255 Broome County Airport	771 Federal Building 100 South Clinton Street

d. History:

Date Constructed 1968 **Date(s)** Reconstructed Never

Designer Soil Conservation Service (U.S.D.A.)

Constructed By Talson Construction

Owner County of Broome

2) Embankment

a. Characteristics

(1) Embankment Material Silty gravel and highly fractured shale and siltstone

(2) Cutoff Type Compacted glacial till

(3) Impervious Core None

(4) Internal Drainage System Two perforated 8 inch BCCMP toe drains on either side of the principal spillway outlet; both pipes flowing ($1\frac{+}{}$ GPM each)

(5) Miscellaneous No comments

b. Crest

(1) Vertical Alignment Excellent; slightly crowned at the center of the dam

(2) Horizontal Alignment Excellent; angled slightly downstream toward the left abutment

(3) Surface Cracks None observed

(4) Miscellaneous Mowed grass

c. Upstream Slope

(1) Slope (Estimate - V:H) 1:3

(2) Undesirable Growth or Debris, Animal Burrows None observed

(3) Sloughing, Subsidence or Depressions None evident

(4) **Slope Protection** Grass, 18 to 24 inches high on entire slope except for riprap at the emergency spillway entrance

(5) **Surface Cracks or Movement at Toe** None evident; footpath along berm at toe of slope

d. **Downstream Slope**

(1) **Slope (Estimate - V:H)** 1:2.5

(2) **Undesirable Growth or Debris, Animal Burrows** None observed

(3) **Sloughing, Subsidence or Depressions** None evident

(4) **Surface Cracks or Movement at Toe** None observed

(5) **Seepage** None observed

(6) **External Drainage System (Ditches, Trenches, Blanket)** None observed

(7) **Condition Around Outlet Structure** Outlet pipe discharges into reinforced concrete impact basin

(8) **Seepage Beyond Toe** None observed

e. **Abutments - Embankment Contact**

Good condition; some slight seepage located on the slope below the berm, just upstream of the right abutment.

(1) **Erosion at Contact** None evident

(2) **Seepage Along Contact** Some seepage from the flat-lying shale of the 1 to 1 rock slope along the right side of the emergency spillway.

3) **Drainage System**

a. **Description of System** Drop inlet structure consisting of a single stage reinforced concrete riser, a 30 inch diameter conduit and a reinforced concrete impact basin.

b. **Condition of System** Excellent

c. **Discharge from Drainage System** Discharge from the impact basin flows over riprap to a grassed channel

4) **Instrumentation** (Monumentation/Surveys, Observation Wells, Weirs, Peizometers, Etc.)

Monumentation of centerline of dam

5) **Reservoir**

a. **Slopes** Gently sloping fields with scattered trees on all sides except the right side and upstream of it which has heavily wooded slopesbecoming moderately steep at and above the design high water level

b. **Sedimentation** Design figures for storage allow for 58.1 acre-feet of sediment

c. **Unusual Conditions Which Affect Dam** Low sediment pool level

6) **Area Downstream of Dam**

a. **Downstream Hazard (No. of Homes, Highways, etc.)** Approximately 2 dwellings are within the dam failure flood hazard area as well as Airport Road and Stella Ireland Road

b. **Seepage, Unusual Growth** None observed

c. **Evidence of Movement Beyond Toe of Dam** None observed

d. **Condition of Downstream Channel** Stable, no aggradation or degradation

7) **Spillway(s) (Including Discharge Conveyance Channel)**

Principal spillway, emergency spillway and discharge conveyance channel

a. **General** Principal spillway and discharge conveyance channel handle normal flows, while the emergency spillway conveys flood events with average return frequencies greater than 100 years.

b. **Condition of Principal Spillway** Very good; however, riprap that has accumulated on the downstream concrete apron of the impact basin should be removed because it will diminish the dissipating effect of the vertical end sill of the basin

c. **Condition of Emergency Spillway** Very good; however, some brush and saplings were growing up through or on the riprap and rockfill slopes which should be removed to prevent this slope protection from becoming dislodged

d. **Condition of Discharge Conveyance Channel** Good the riprap is stable; however, there are several areas of minor erosion of the left bank, one in particular where the channel slope has slid downward.

8) **Reservoir Drain/Outlet**

Type: **Pipe** Two **Conduit** _____ **Other** _____

Material: **Concrete** X **Metal** X **Other** _____

Size: Concrete: 30 inch, Metal: 12 inch **Length** 230 feet and 41 feet

Invert Elevations: **Entrance** 1233.5 **Exit** 1226.5

Physical Condition (Describe): **Unobservable** _____

Material: Prestressed concrete cylinder and cast iron

Joints: Rubber/steel and mechanical **Alignment** Straight

Structural Integrity: Excellent

Hydraulic Capability: Good

Means of Control: **Gate** Slide Gate **Valve** _____ **Uncontrolled** _____

Operation: **Operable** X **Inoperable** _____ **Uncontrolled** _____

Present Condition (Describe): Each pipe is in excellent condition

9) **Structural**

a. **Concrete Surfaces** Excellent condition

b. **Structural Cracking** None observed

c. **Movement - Horizontal & Vertical Alignment (Settlement)** None evident

d. **Junctions with Abutments or Embankments** Not applicable

e. **Drains - Foundation, Joint, Face** See Section 2) Embankment, a. Characteristics, (4) Internal Drainage System

f. **Water Passages, Conduits, Sluices** 12 inch slide gate on the reservoir drain at its inlet to the reinforced concrete riser

g. **Seepage or Leakage** None observed

h. **Joints - Construction, etc.** Rubber and steel joints on the 30" prestressed concrete cylinder pipe and mechanical joints on the 12" reservoir drain

i. **Foundation** Not applicable

j. **Abutments** Not applicable

k. **Control Gates** 12" slide gate on the reservoir drain at its inlet to the reinforced concrete riser

l. **Approach & Outlet Channels** Not applicable

m. **Energy Dissipators (Plunge Pool, etc.)** Reinforced concrete impact basin at the principal spillway outlet

n. **Intake Structures** Reinforced concrete riser having two sides acting as weirs having a total length of 6 feet, 8 inches

o. **Stability** No evidence of structural instability

p. **Miscellaneous** No comments

10) Appurtenant Structures (Power House, Lock, Gatehouse, Other)

a. Description and Condition None

DESIGN REPORT

SITE 2B

BROOME COUNTY, NEW YORK

U S DEPARTMENT OF AGRICULTURE
SOIL CONSERVATION SERVICE

U S DEPARTMENT OF AGRICULTURE — SOIL CONSERVATION SERVICE

This floodwater retarding structure is located on Little Choconut Creek approximately 4.5 miles north of Johnson City, New York. Sheet 4 of this report, together with the Castle Creek, N.Y. 7.5' quadrangle published by the U. S. Geological Survey, may be used to locate this structure.

A summary of pertinent design information is given on Sheet 2 of this report.

Criteria and procedures used in this design are given in Soil Conservation Service publications.

This is one of eight proposed floodwater retarding dams in the Little Choconut, Finch Hollow, and Trout Brook Watershed designed to reduce floodwater damages. It will retard a 100-year frequency storm without discharge occurring in the emergency spillway.

The results of hydrologic and hydraulic computations are given on Sheet 3 of this report.

The structure consists of a compacted earth fill with a cutoff trench through the Sp-Sm material in the flood plain and into the glacial till in both the flood plain and left abutment and into firm bedrock in the right abutment. A drainage system is located under the downstream portion of the earth fill to control the phreatic surface and provide a safe outlet for foundation seepage.

The principal spillway is a drop inlet structure consisting of a single stage reinforced concrete riser, a 30 inch diameter reinforced concrete water pipe, and a reinforced concrete impact basin to dissipate the energy of high velocity discharge at the outlet end of the conduit.

The emergency spillway is an earth and rock cut in the right abutment. An engineering cost analysis was performed which resulted in the least combined cost of fill and emergency spillway rock excavation.

This site is located approximately 5 miles due north of the city of Johnson City, New York. The Susquehanna River flows westerly along the southern edge of Johnson City at this point and is about 7 miles north of the New York-Pa. state line.

The topography of the area ranges from 810' in the Susquehanna River to 1500' plus in the vicinity of this site. The total relief is less today than it was pre-glacially, owing to aggradation of till on the uplands and valley sides and deposition of outwash and alluvial materials in river channels. This site is a good example of outwash and alluvial materials filling a pre-glacial valley.

Glacial ice had little effect on the topography in this area. The ice sheet was relatively thin, extending only some 40 miles south of the Binghamton area.

The underlying bedrock is Upper Devonian in age and is almost exclusively shales and siltstones of the Catskill Delta.

The geologic history of this site appears to be one of glacial scour of the north-facing valley wall (right abutment) and filling of the pre-glacial valley with lacustrine and alluvial deposits. Apparently, there has been some corrasion of the

bedrock in the lower elevation of the right abutment. Drill holes and test pits reveal the development of a shelf in the bedrock surface at about present stream bed elevation. This situation is further verified by the enhanced steepness of the abutment for a vertical distance of 30' or so above this shelf. This condition has been noted on other sites in this area and verified by drilling.

Drill Rig	4	4	20' of NX core	--	47 (Jar)
	10	4	20' of NX core	--	47 (Jar)

SUMMARY OF FINDINGS

The left abutment of this site is a fairly uniform glacial till. This uniformity extends down to the area of the principal spillway, and to a depth of at least 30' at DH 51.

In the floodplain, the till is replaced by a moderately dirty gravel to an average depth of 3'. This gravel is underlain by a 3'-5' layer of stiff clay. Under the clay, a moderately thick zone of coarse sand extends to below backhoe depth. DH 52 went through this sand and back into till, with bedrock being encountered at a depth of approximately 33'.

The sand is carrying a lot of water. Seepage is heavy in backhoe pits excavated in this material.

On the right side of the floodplain, the backhoe trench revealed the bedrock surface rising steeply from its location at DH 52 to within 4' or so of the surface. It forms a definite bench at this level and then follows parallel with the ground surface to a point beyond the emergency spillway excavation. The average depth to bedrock over this entire abutment is about 3'.

The bedrock encountered in this investigation is predominantly a siltstone with zones of softer shale. Several thin beds of very fine grained sandstone are mapped in the type section of this Rhinestreet Formation and were also logged in some of the drill holes on this site. Whereas, the overall picture of bedrock in this section of the state indicates a very gentle dip to the SW, in this immediate vicinity the strata dip S 60 W at a rate of about 90' to the mile.

A well developed set of north-south oriented joints exists in the bedrock in this area. This pattern is intersected by a less well developed east-west trending set.

DETAILED GEOLOGIC INVESTIGATION OF DAM SITES

Total	7	3	--	2	26 (Jar)

SUMMARY OF FINDINGS

(Include only factual data)

The two 20' drill holes located in the area of the riser and outlet structure were logged as 11'-13' of very dense till, underlain by 1'-2' of very silty gravel or clay. Below this, dense till was again encountered to a depth of 20'. The backhoe pit at the intersection of the C/L of dam and the principal spillway was also logged as 8' of dense till with one large 3'-4' boulder in the pit.

Backhoe	6	2	--	2	--
Total	6	2	--	2	--

SUMMARY OF FINDINGS

(include only factual data)

The supplemental borrow area is located approximately 500' upstream from the C/L of the dam, on the left abutment. There are 8 acres of suitable borrow in this area, with a useable depth of 9'+. This will provide approximately 115,000 cubic yards of fill.

The material grades imperceptibly from a GM (silty gravel) to a CL (clay) with a high percentage of coarse material. Occasional large (2'-3') boulders were encountered in the test pits in this area.

Total					

SUMMARY OF FINDINGS

(include only factual data)

Drain Line

Three backhoe pits were dug in the vicinity of the drain line. Representative samples of the material were taken and processed for filter design.

Water Supply

This stream has a good base flow. During the investigation, the driller was able to pump steadily from a sump in the channel bottom at a steady rate of 50 g.p.m.

Other Materials

The bedrock in the emergency spillway excavation will not make durable riprap. It is, however, possible that it may be suitably incorporated in the fill.

Natural drainage materials are absent on this site or occur in locations that do not make them readily available.

INTERPRETATIONS AND CONCLUSIONS

Centerline of Dam

The left abutment of this site, from the top of dam down to about the principal spillway location, is a fairly uniform glacial till.

There was little or no seepage observed in any of the test pits in this area. The till is quite dense, with moderately high blow count logged to a depth of 30 feet in D.H. 51.

In the flood plain, we have about 3 feet of dirty gravel, underlain by approx. 4 feet of stiff clay. In the backhoe pits, a coarse sand under the clay is carrying a lot of water and caves quite readily. The stiff clay and the upper portion of the sand runs a little below 20 blows/ft., but I don't feel it is significant with respect to consolidation for this fill height.

D.H. 52 encountered bedrock at 33 feet. This rock surface rises steeply under the stream and forms a shelf between the stream and the base of the right abutment. From this point and on up the right abutment, the bedrock surface is a fairly uniform 3-4' below ground surface. Differential settlement will undoubtedly occur in the zone adjacent to the bedrock surface between the shelf and the stream. We do have some plastic material available for borrow and conceivably could selectively place this material in this location.

Pit 1 was dug as a trench from the base of the abutment out toward the stream. We were able to cut through 2 feet or so of the bedrock before encountering "solid" rock. I assume that this same condition exists in the elevation zone between the flood plain and the emergency spillway.

The base of the coarse sand is shown at a depth of 14 feet in D.H. 52. This is an indicated guess. The groundwater table, while not well defined, is either at the top of this sand or in the overlying clay. Seepage water in the surface gravel is undoubtedly influent from the stream and partially perched above the main table. The same old problem of trying to correlate spoon samples with backhoe pit logs in some materials was present here. In this case, I believe the 2" spoon driven into this material had a tendency to consolidate it and incorporate some of the fines from wash and seepage water. We were just unable to get the same material out of these spoon samples. Therefore, I am not just sure where it does end.

In any event, the 14 foot depth is probably conservative. The problem of consideration of cutoff depth is tied in with this. It is my feeling that a cutoff through this material is not feasible. Excavation will be difficult at best and we could wind up with a top width of the cutoff trench approaching the base width of the dam! (This is of course an exaggeration, but it could be a big one.) I would like to suggest then that consideration be given to allowing water to pass through this sand and be picked up downstream with a good sized drain. If this is done, then we could get by with a shallow cutoff in the left abutment; through material A in the flood plain and down to "solid" rock in the right abutment and on the rock shelf in the flood plain. It should

State New York County Broome Name L. Choconut

Site number 28 Class C Structure class , Geologist 10/65

INTERPRETATIONS AND CONCLUSIONS (continued)

be pointed out that it may be difficult to cut this trench to a uniform "neat" line. The excavation characteristics of this interbedded siltstone and shale with occasional fine-grained sandstone is such that we may wind up with a series of benches in the profile.

The design of the drainage material should be based on samples #302.1 and 302.2. It should probably be extended down into the sand a couple of feet to provide a little more intake area as well as removal of any contamination from fines in the overlying CL material. I do not have any information on the specific permeability of these sands, except that it is high. The size of the drainage system should definitely be large enough to carry the extra seepage induced by raising headwater behind the structure.

There is some indication of minor seepage in the bedrock in the right abutment, but no well defined seep areas were noted during this investigation.

Principal Spillway

Several locations were investigated for the principal spillway. These locations are defined by the test pits on the plan view.

It appears that the best location will be the one shown on the plan view of the structure, located approx. 10 feet left of the line through B.H. 351 and 352. This arrangement should keep the pipe etc. off the softer clay underlying the major portion of the floodplain.

The material under the extent of the pipe is a dense till, uniform in strength and depth. Some excavation will have to be done at the riser and outlet structure location but this should not be a big cost item.

Emergency Spillway

The emergency spillway excavation will, of course, be in rock. The State Conservation Engineer has studied the rock cores and recommendations for design will not constitute a part of this geology report.

Suitability of the rock excavated from the spillway, for incorporation in the fill, will be determined from the results of tests performed on cores submitted to the Lincoln Lab. Photographs of the weathering characteristics of the rock are a part of this report. Test shows cuts that are approx. 25 years old and represent the range of rock that we may expect in the spillway excavation.

State New York County Broome Watershed L. Choconut

Site number 2B Site group C Structure class Investigated by , Geologist 10/65

INTERPRETATIONS AND CONCLUSIONS (continued)

Borrow

There will be approximately 2,000 cu. yds. of overburden material available from the emergency spillway excavation. This is represented by samples #202.1 and 209.1.

A separate borrow investigation was made for this structure. Two representative samples of the material were obtained (103.1 and 104.1). They indicate the range in this material, from a GM to a CL. This variation apparently occurs as a gradational change, rather than an abrupt one. The materials cannot, therefore, be segregated in the field with any degree of certainty. We can probably effect informal zoning by some selective placement, but I feel the embankment should be tested and designed for the lower strength of these two borrow samples and as a homogeneous fill.

REVIEW AND INTERPRETATION OF DATA

FOUNDATION MATERIALS

A. Bedrock: Bedrock consists of siltstone and shale. It is close to surface (3' to 4') in the right abutment. It drops off to 33' in Test Hole No. 52 and was not drilled to the left of that station (stationing not shown). The rock is jointed and relatively thin bedded.

B. Soil Classification: No centerline samples of floodplain materials were submitted. Both the clayey material, zone 'B', and the sand below it, zone 'C', are represented by grain size distribution graphs and Atterberg tests furnished with the geologic report. The clay classes as a CL and the sand as SM-SP. The description states the floodplain is "dirty gravel" to about a 3' depth which is underlain by "3' to 5' of stiff clay". This is a very fine lacustrine material as shown by the gradation from the laboratory at Syracuse.

Under the lacustrine clay, is a zone of coarse sand of variable thickness ranging from 5' to 7' which was classed as SP-SM from a gradation made in Syracuse. In Drill Hole No. 52 this material contained more plastic fines.

The left abutment is all a fairly uniform, dense till which is represented by Sample 66W1920 (103.1), a low-plastic GM. This till

appears to extend under the left side of the floodplain as the rock contact continues to drop.

Water table was not recorded, but seepage was noted in the SP-SM, zone 'C', and up into zone 'B'.

C. Dry Unit Weight (Blow Count): No density tests were made, but blow count is quite high. This would indicate high strength if all materials were saturated. Since the CL in zone 'B' appears to be saturated, it is probably dense and strong. In-place density tests should be made, if there is any doubt. The material should be tested, if the density is not high, instead of taking chances on a dam with high damage classification.

D. Consolidation: Based on blow count and classification, an estimate of 0.03 ft./ft. is made as an average for 12' of foundation. Use 0.04' as a conservative maximum.

Consolidation under the conduit at its proposed location will be practically negligible. The differential consolidation near the right abutment is not expected to be great enough to cause tension cracks in the moderately plastic center section material.

E. Permeability: The till and the CL shown as zone 'B' are described as very low in permeability. The surface GM is probably moderately permeable and the SP-SM is described as very permeable. Based on its gradation alone, a rate of k = 100+ ft./day might be expected, but its high density indicates half that rate might be more applicable.

Permeability of the rock was not discussed. The well formed joint pattern would indicate some seepage, but probably not great below the severe surface weathering.

F. Shear Strength: Based on the blow count and classification, it appears that any embankment failure would be limited to the base of zone 'B' or to the embankment only. We have very little basis for assessing the strength of the CL (zone 'B'), if that zone was not saturated when the blow count was taken.

EMBANKMENT MATERIALS

A. Classification: Embankment samples submitted consisted of a low plastic GM, a fairly plastic CL sample, and a GC-GM sample. There is very little material represented by the GC-GM. The GM and the CL, together, account for 100,000 cu. yds. No estimate was made as to how much of

each is available. It appears they can be separated but only on a selective basis, as borrowing proceeds.

No estimate was made on the quantity of rock available. If the spillway is placed as shown on cross sections, about 13,000 cu. yds. would seem to be available. It would appear that about 4,000 cu. yds. may be quite durable as rock fill.

B. Compacted Dry Density: Standard Proctor compaction tests (ASTM D-698) on the minus No. 4 size fraction yielded maximum dry densities of 119.5 pcf for the GM and 117.5 pcf for the CL. The GC-GM was not tested.

It is estimated that the hard portion of the spillway rock excavation may provide a relatively clean rock fill that would be placed at about 115 pcf. The softer materials should compact to an acceptable degree under an equipment use specification. If a method specification is not acceptable, it will be necessary to test large size samples at field moisture conditions or build and test some test fills to determine mass density specifications.

C. Permeability: The till material in the center section should be nearly impermeable at 95% of standard density.

The softer shale fill should be only slightly permeable, but the harder rock material would form a relatively permeable fill, if it can be separated.

D. Shear Strength: Consolidated, undrained, triaxial shear tests were made on the minus No. 4 screen gradation of the GM till Sample 66W1920 and on the CL till Sample 66W1921. The specimens were molded at 95% of standard density and tested at near saturation. The degree of saturation varied for Sample 66W1920, and it is hard to interpret an actual total stress envelope, but the material is certainly strong. It could be any place from $\phi = 31°$, $c = 300$ psf to $\phi = 24°$, $c = 1050$ psf. The results on the CL are $\phi = 18°$, $c = 875$ psf at a high degree of saturation. This is considered as a limiting strength.

E. Consolidation: No tests were made. No more that 2% of the fill height should be anticipated for settlement within the fill itself due to residual consolidation.

SLOPE STABILITY ANALYSIS

Downstream slope stability was checked with one arc by a circular failure method. A safety factor of 2.2 was computed against steady seepage,

impinging on the slope at a height of about one-third the reservoir head.

The stability of a 3:1 slope against full drawdown would be as good, so no other trials were made.

SETTLEMENT STRAINS

Settlements within the foundation materials will be low and no problem of settlement strains is anticipated.

ROCK SOUNDNESS

Visually from inspection of rock cores and from pictures of exposed rock faces, it is evident that rock hardness and durability are quite variable.

Bulk dry density of specimens tested varied from 159 pcf to 164 pcf.

Absorption varies from 2% to 3%.

Percentage of loss under five cycles of sodium sulfate soundness test, Federal Specification-SS-R-406 (Method 203 - Ledge Rock), varied from 56.9% to 73.8%. The losses came from complete disintegration of many soft specimens, but very little loss from hard ones.

CONCLUSIONS AND RECOMMENDATIONS

A. Cutoff: A positive cutoff is attainable but is not believed to be necessary or economically advisable.

Cutoff is recommended through the gravelly surface in the floodplain to bottom at about a 4' to 5' depth in the lacustrian CL. On the abutments it should be about the same depth and bottom in relatively unweathered rock on the right abutment and in dense till on the left abutment.

Use care to prevent drying cracks and slaking in the exposed shale or fine lacustrine materials during construction.

Backfill with select plastic till material placed at 95% of standard or better with moisture controlled at or above optimum.

B. Principal Spillway: The proposed location provides for a good foundation condition.

The pipe cradle can be set on dense till or lacustrine material.

A stilling basin can be cut into the compact till and little seepage

is anticipated.

Foundation consolidation will be a minimum, and normal pipe joints and no camber are recommended in this case.

Use $\phi = 35°$ to represent the strength of moist fill in conduit loading computations.

C. Drainage: A drain is recommended to relieve uplift and prevent piping. A trench drain at c/b = 0.6 with a perforated pipe outlet is suggested.

It should bottom well into the sandy, gravelly, zone 'C' materials across the floodplain and into the weathered rock surface of the right abutment. In the till of the left abutment a 4' depth will suffice.

The drain should extend laterally up to elevation 1250 in both abutments and should completely encompass the conduit at their intersection.

Samples were not available to completely define the filter needed, but based on the SP-SM gradation of Field Sample 302.2 made at the Syracuse laboratory, a uniform filter gradation of No. 8 screen size to 1" would be desirable. This can be used with 3/8" pipe slots.

D. Embankment Design: The following are recommended:

1. Place the till selectively to use the most plastic as a center section.

   Use the shale and siltstone from the emergency spillway excavation in the downstream slope. (See Form SCS-372.) It should be protected from surface exposure by a blanket of till, except at the toe of the slope, where a selected section of the most durable rock may be placed as a drainage feature.

2. Place the till at 95% of Standard Proctor density, based on the minus No. 4 screen size material.

3. Provide a 3:1 upstream slope with berm and a 2 1/2:1 downstream slope as proposed.

4. Provide overfill of 1.0' across the floodplain section to compensate for residual settlement in the fill and foundation.

E. Emergency Spillway: The rock nature is such that soft materials will weather and slake with time.

6 -- W. S. Atkinson -- 3/8/66
Rey S. Decker
Subj: ENG 22-5, New York WP-08, Little Choconut, Site No. 2-B

Hard members are resistant and appear to be numerous enough so that danger of serious damage to the control section should not be great during any one storm event, even at 11 feet per second velocity.

This danger can be minimized by use of a wider control section and by judicious placement as the spillway excavation proceeds.

RECEIVED
ASST. SUPT.
CHIEF, OPER. & MAINT.
WATERSHED DIVISION

TO: Mr. J. R. Stellato
Acting Asst. Supt. of Oper. & Maint.

Attention: Mr. A. Dickinson

FROM: Mr. Wm. P. Hofmann, Director
Bureau of Soil Mechanics

SUBJECT: Finch Hollow, Little Choconut & Trout Brook Watershed Project
Floodwater Retarding Dam No. 2-B
Broome County

Referred to:
[illegible]
[illegible]tion
[illegible]
[illegible] Plant
[illegible]
[illegible]
File

In accordance with your request, we have reviewed the design of the above floodwater retarding dam from the soil mechanics standpoint. Our review was based on the information contained in plans and specifications prepared by the Soil Conservation Service of the U.S. Department of Agriculture.

We offer the following comments and recommendations to the plans and specifications:

1. Sheet two of the plans indicates a supplemental borrow area upstream of the dam. It is our opinion that no borrow should be allowed within a distance of four hundred (400) feet of the C/L of the dam.

2. As the zoned dike on Sheet 5 is presently designed, it is possible that water pressure could build up at the interface of zone 1 and zone 2 due to a heavy rainfall or a sustained flow through the emergency spillway. We recommend that a positive method of drainage be incorporated in the plans to alleviate this condition.

3. The drainage trench or toe drain would be better located approximately halfway between the centerline and the downstream toe of the dam. This change is recommended to improve the seepage conditions in and beneath the dam.

4. In order to prevent possible future settlements, the drain fill in the area of the impact basin should be compacted.

We are returning the plans, specifications and various reports for this dam but request that any revised information based on the above recommendations be again made available for our review.

Wm. P. Hofmann, Director
Bureau of Soil Mechanics

PREVIOUS INSPECTION REPORTS

UNITED STATES DEPARTMENT OF AGRICULTURE

SOIL CONSERVATION SERVICE

Chemung County Rural Urban Center, P.O. Box 353, Breesport, N.Y. 14816

SUBJECT ENG - 40 Inspection of Dam Sites; Nanticoke 9A, Little Choconut 2C, 6B, 2E

DATE September 19, 1979

TO Herbert J. Lyford, Area Conservationist

On September 11, 1979 and September 12, 1979, I inspected the above structures to conform to Administrator's General Memorandum-16. Dick Crowe and Dan Walker accompanied me on the 11th and only Dan Walker on the 12th.

Hazard classification was not reviewed since all the structures were already hazard class C.

Overall the operation and maintence was good. The only item I question is whether the mowing of the dam slopes will eventually kill the crown vetch. I understand that crown vetch should not be mowed annually.

On all structures the condition of the principal spillway system was the major item inspected. The slopes of the dam and the emergency spillway were looked at for any seeps or slips.

I did not have copies of the construction as-builts or of previous inspection reports available when the inspections were made. I recommend that these be on site during future inspections.

All the sites inspected with impact basins had evidence of deterioration of the joint filler around the outlet of the conduit. This should be checked annually for loss of soil from behind the back wall of the impact basin.

Attached are the individual reports for the above structures.

Dana C. Chapman, P.E.
Project Engineer

WATERSHED Clermont SITE NO. 2B DATE OF INSPECTION [illegible] DATE OF LAST INSP. _____

SPONSOR WITH OPERATIONS AND MAINTENANCE RESPONSIBILITY Barnes SWCD

PRESENT HAZARD CLASSIFICATION C NEW CLASSIFICATION IF WARRANTED C

O & M ITEMS	SATISFACTORY/UNSATISFACTORY • EXPLANATION
1. VEGETATION	
a.) Mowing	S /a.)
b.) Reseeding	S /b.)
c.) Fertilising	S /c.)
d.) Excessive other uses	S /d.)
2. FENCING	
a.) Intact and Functional	S /a.)
b.) Debris in Fence	S /b.)
c.) Gates, Locks	S /c.)
3. EMERGENCY SPILLWAY	
a.) Erosion	S /a.)
b.) Excessive Seepage	S /b.)
c.) Sedimentation	S /c.)
d.) Obstructions in Channel	S /d.)
e.) Slips, Slides; Location	S /e.)
4. EMBANKMENT	
a.) Cracking, excessive settling	S /a.)
b.) Erosion	S /b.)
c.) Seepage	S /c.)
d.) Other Damage (Rodents...)	S /d.)

O & M ITEMS	SATISFACTORY/UNSATISFACTORY - EXPLANATION
5. RESERVOIR AREA	
a.) Undesirable Vegetation	S * /a.) CATTAILS
b.) Cut or Fallen Trees	S /b.)
c.) Debris/Slash	S /c.)
d.) Sedimentation	S /d.)
6. OUTLET CHANNEL	
a.) Sedimentation	/a.)
b.) Cutting and Scouring	S /b.)
c.) Woody Growth	/c.)
7. ROCK RIPRAP	
a.) Undermining	/a.)
b.) Adjacent Channel Scouring	/b.)
c.) Deterioration	/c.)
8. TRASH RACKS, GRATINGS	
a.) Accumulated Debris	S /a.)
b.) Broken or Missing Parts	S /b.)
c.) Galvanising or Paint	S /c.)
9. OTHER SPECIAL STRUCTURES	
a.) Diversions	/a.)
b.) Access Roads	S /b.)
c.) Waterways	S /c.)
d.) Other, list.....	/d.)
e.) Other, list.....	/e.)
10. PRINCIPLE SPILLWAY	
a.) Riser	
1.) Condition of Concrete	S /1.)
2.) Seepage and Cracks	S /2.)
3.) Condition of Transition	S /3.)

O & M ITEMS	SATISFACTORY/UNSATISFACTORY - EXPLANATION
10. PRINCIPLE SPILLWAY	
b.) Impact Basin	
1.) Condition of Concrete	S /1.)
2.) Sedimentation, Debris	S /2.)
3.) Pipe Entrance Condition	S /3.) CRACK AROUND PIPE @ E
c.) Plunge Pool	
1.) Riprap Condition	S /1.)
2.) Vegetative Treatment	S /2.)
d.) Drain System	
1.) Seepage (Clean, Dirty)	S /1.)
2.) Animal Guards	S /2.)
e.) Pipe	
1.) Cracks, Seepage	/1.)
2.) Debris and Sedimentation	/2.)
3.) Listing of gaps greater than 3/8 inch.	Maximum joint extensibility

JOINT #	
12 O'Clock	
3 O'Clock	
6 O'Clock	
9 O'Clock	

Gap locations as looking downstream.

11. GATES AND VALVES

Estimated leakage with gate closed and adjusted ~2 gpm.

General description of system GATE IS SLUICE GATE

Operational Check: Satisfactory ✓ UNSATISFACTORY

12. PUMP SYSTEMS

General condition report, including operations record, fuses broken or missing, broken or missing warning lights, faulty switches, lubrication required, excessive vibration:

12. PUMP SYSTEMS

General condition report, continued:---------

13. SAFETY

List all hazards present: (including broken guards, rails, rope swings, diving boards on risers, evidence of pollution, garbage)

RECOMMENDED REPAIRS AND METHOD OF REPAIR: Remove cattails & sediment from pool area. Repair fence on west side. Remove & haul away debris.

INSPECTED BY R. Wilson

TITLE District Manager

DUTY STATION Bainbridge F.C.

NOTE: DESIGNATE NOT APPLICABLE ITEMS BY MARKING N/A.

DAM INSPECTION REPORT
(By Visual Inspection)

Dam Number	River Basin	Town	County	Hazard Class*	Date & Inspector
96A-3630	Susq.	Maine	Broome	B	5/28/76 KVH

Type of Construction

- ☐ Earth w/concrete spillway
- ☑ Earth w/drop inlet ~~pipe~~ Conc.
- ☐ Earth w/stone or riprap spillway
- ☐ Concrete
- ☐ Stone
- ☐ Timber

Use

- ☐ Water Supply
- ☑ ~~Power~~ Flood Control
- ☐ Recreation
- ☐ Fish and Wildlife
- ☐ Farm Pond
- ☐ No Apparent Use-Abandoned

Estimated Impoundment Size

- ☐ 1-5 acres
- ☐ 5-10 acres
- ☑ Over ~~10~~ acres 30 Max.

Estimated Height of Dam above Streambed

- ☐ Under 10 feet
- ☐ 10-25 feet
- ☑ Over 25 feet 45'

Condition of Spillway

- ☑ Service satisfactory
- ☐ In need of repair or maintenance
- ☑ Auxiliary satisfactory
- ☐ In need of repair or maintenance

Explain: _____

_____

Condition of Non-Overflow Section

- ☑ Satisfactory
- ☐ In need of repair or maintenance Explain: _____

_____

Condition of Mechanical Equipment

- ☑ Satisfactory
- ☐ In need of repair or maintenance Explain: _____

_____

Evaluation (From Visual Inspection)

- ☑ No defects observed beyond normal maintenance
- ☐ Repairs required beyond normal maintenance

*Explain Hazard Class, if Necessary _____

GENERAL NOTES

1. AREAS UNDER THE DAM, THE EMERGENCY SPILLWAY, AND SUPPLEMENTAL BORROW AREA TO BE CLEARED AND GRUBBED. LIMITS OF AREA TO BE CLEARED AND GRUBBED SHALL BE STAKED IN THE FIELD BY THE ENGINEER (SPEC 2B)
2. AREA UPSTREAM FROM DAM AND BELOW ELEVATION 1243.0 (MSL) SHALL BE CLEARED. LIMITS OF AREA TO BE CLEARED SHALL BE STAKED IN THE FIELD BY THE ENGINEER (SPEC 1B)
3. ALL FENCES IN WORK AREA TO BE DISPOSED OF AS STRUCTURAL REMOVAL. (SPEC 3A)
4. TOPSOIL THAT IS SUITABLE FOR USE WILL BE INCORPORATED WITHIN THE SLOPES OF THE EARTH FILL AS DIRECTED BY THE ENGINEER.
